CIS 678 – Machine Learning

Project 5

Abstract

With our final project in CIS 678 – Machine Learning, we implement a genetic algorithm (GA) to find the global minimum of two complex functions: Rosenbrock's Banana function and Goldstein-Price function.

Implementation

Our program is written in Python 2.7 and bash scripting in Unix. These programs were executed locally on each member's respective Macbook Pro (2012), testing on eos23 and okami.

Background

Two in-class datasets involved fishing, but testing was too variable with too few observations

Results

An example of our output can be seen in Figure 1. The parameters to the program include in order: population size, number of chromosome bits, function range min, function range max, number of function inputs, function of choice, number of generations, and percent of parents to keep.

```

```

Figure 1. Example output of GA.

In Figure 1, we find with 1000 sized population, 32 chromosome bits, 128 number of generations, and 10% of the parents kept around after each generation, our GA finds the global minimum with accuracy to the fifth decimal place. In Figures 2 and 3, we observe the effect population size has on GA convergence, as not until log base 2 of 8 (256) sized population shows convergence. In Figures 4 and 5, we see that GAs do not converge well given under 32 chromosome bits. We find with Figures 6 and 7, that at least 32 generations are needed for convergence for Goldstein and 64-128 generations were needed for Rosenbrock. Inconsequentially, Figure 8 shows us that the percentage of parents kept after each generation from 1% to 99% is negligible with 50 generations and 1000 sized population.
